Forest Service

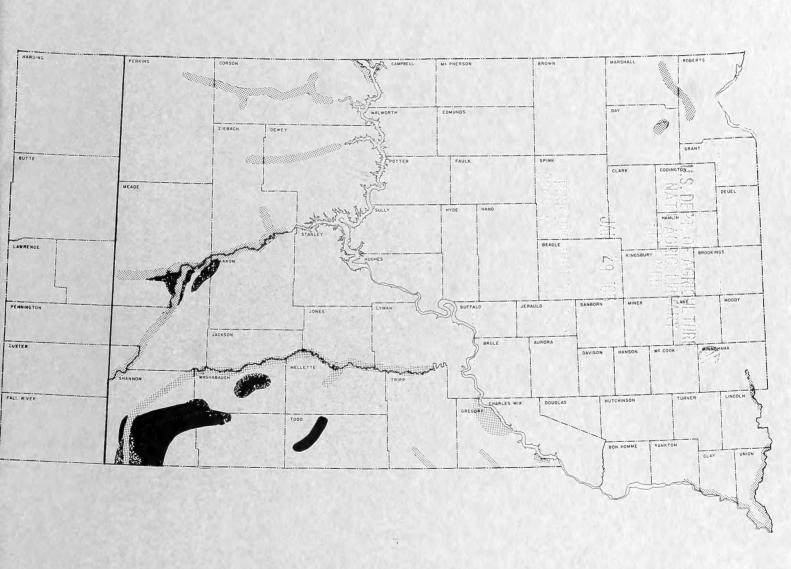

North Central Forest Experiment Station

Resource Bulletin NC-74

Eastern South Dakota Forest Statistics, 1980

Gerhard K. Raile

Information contained in this report includes the most commonly used Forest Inventory and Analysis (FIA) statistics. However, additional forest resource data can be provided to interested users. Persons requesting additional information that can be provided from the raw inventory data are expected to pay for the retrieval costs. These costs will vary depending on the complexity of the request, from less than \$100 for a simple request to \$2,000 for a complete retrieval involving the services of an FIA computer programmer. If requests for data conflict with ongoing work, they will be scheduled so as to minimize the impact on the work unit.

FOREWORD

Forest Inventory and Analysis (FIA) is a continuing endeavor as mandated by the Forest and Rangeland Renewable Resources Planning Act of 1974. Prior inventories were mandated by the McSweeney-McNary Forest Research Act of 1928. The objective of FIA is to periodically inventory the Nation's forest land to determine its extent, condition, and volume of timber, growth, and depletions. Up-to-date resource information is essential to frame intelligent forest policies and programs. USDA Forest Service regional experiment stations are responsible for conducting these inventories and publishing summary reports for individual States. The North Central Forest Experiment Station is responsible for Forest Inventory and Analysis work in Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, eastern South Dakota, and Wisconsin.

Fieldwork for the 1980 eastern South Dakota¹ Forest Survey began in June 1980 and was completed in July 1980. Previous surveys of eastern South Dakota timber resources are dated 1935 and 1965. Eastern South Dakota is the land east of the 103rd meridian as shown on the front cover map.

The forest resources of western South Dakota² were surveyed in 1983 by the Intermountain Forest and Range Experiment Station, Odgen, Utah. A report analyzing the timber resources of the entire State will be published by that Station.

Aerial photos used in this Inventory were furnished by USDA Agricultural Stabilization and Conservation Service, Huron, South Dakota.

¹East of the 103rd meridian.

²West of the 103rd meridian.

EASTERN SOUTH DAKOTA FOREST STATISTICS, 1980

Gerhard K. Raile, Mensurationist

HIGHLIGHTS

Area

- Forest land area totaled 266,300 acres—0.6 percent of the Unit's total land area.
- Fifty-five percent of the Unit's forest land is unproductive forest.
- Commercial forest land decreased by 31 percent between 1965 and 1980, from 165,400 to 113,600 acres.
- Farmer and Indian owners account for 91 percent of the Unit's commercial forest land—farmers alone own 57 percent.
- Seventy-two percent of the commercial forest land is in the elm-ash (45,500 acres), cottonwood (18,500 acres), and ponderosa pine (17,800 acres) forest types.
- Sawtimber stands account for 42 percent of the commercial forest followed by poletimber stands (23 percent), sapling and seedling stands (22 percent), and nonstocked areas (13 percent).
- Stands between 30 and 81 years of age occupy 49 percent of the commercial forest.
- Fifty-eight percent of the commercial forest is poorly stocked with growing-stock trees (16.7 to 60 percent), 21 percent is medium stocked (61 to 100 percent), and 9 percent is well stocked (101 to 133 percent).
- Wooded strips occupy 160,000 acres. Wooded strips do not include windbreaks and would be commercial forest except for width.
- Windbreaks amount to 127,800 acres and are part of the 601,100 acres of nonforest land with trees in the Unit.

Volume

• The total volume of timber on commercial forest land in 1980 was 76.9 million cubic feet—51.9 million in growing-stock trees, 22.7 million in rough

- and rotten trees, and 2.3 million in salvable dead trees.
- Growing-stock volume decreased 42 percent from 89.6 million cubic feet in in 1965 to 51.9 million cubic feet in 1980.
- Growing-stock volume per acre decreased 16 percent from 541.7 cubic feet in 1965 to 456.9 cubic feet in 1980.
- Sawtimber volume per acre decreased 10 percent from 1,728 board feet to 1,553 board feet in 1980.
- Elm growing stock took a drastic drop due to Dutch elm disease—from 15.6 million cubic feet in 1965 to 3.9 million cubic feet in 1980. The drop in elm sawtimber volume was even more significant—from 58.0 million board feet in 1965 to 7.8 million board feet in 1980.
- Cottonwood is the species with the most sawtimber volume on commercial forest land (44 percent of the total), followed by ponderosa pine (22 percent) and ash (18 percent).
- Farmers own 57 percent of the growing-stock volume (29.7 million cubic feet), and Indians own 33 percent (17.3 million cubic feet).
- The elm-ash type accounts for 35 percent of the growing-stock volume, the cottonwood type for 31 percent, and the ponderosa pine type for 21 percent.
- The cottonwood type has the most sawtimber volume per acre with 3,659 board feet.
- Sawtimber volume by butt log grade is concentrated in log grade 3 (64 percent of sawtimber volume).

Stand Conditions

- Net annual growth of growing stock amounted to 1.5 million cubic feet in 1979, 2.8 percent of inventory.
- Sawtimber growth was 7.5 million board feet in 1979, 4.3 percent of inventory.
- Mortality of growing-stock trees totaled 176,000 cubic feet in 1979, 0.3 percent of inventory.

• Disease accounts for 57 percent of the mortality.

Timber Use

- Timber removals from growing stock totaled 1,762,000 cubic feet in 1979—679,000 for roundwood products, 57,000 for logging residue, and 1,026,000 for other removals.
- Removals of growing stock for 1979 are 45 percent lower than those in 1964.
- Farmers and miscellaneous private individuals owned 98 percent of the 1979 growing-stock removals.
- Sawtimber removals from commercial forest land totaled 5.6 million board feet in 1979, 41 percent lower than in 1964.
- Growing-stock removals for roundwood products totaled 679,000 cubic feet, 50 percent as firewood and 45 percent as saw logs.
- Wood residue from primary plants amounted to 116,100 cubic feet—23 percent of it was not used.

Biomass

- Live tree biomass (trees greater than 1 inch in d.b.h.) totaled 3.7 million green tons, or 32 tons per acre of commercial forest land.
- Highest yields per acre of live tree biomass are in the cottonwood type (49 tons) and the oak type (34 tons).
- Sixty percent of the live tree biomass is in the boles of trees greater than 5 inches d.b.h., 31 percent is in the tops and limbs of these trees, and 9 percent is in trees less than 5 inches d.b.h.

APPENDIX

ACCURACY OF SURVEY

Forest Inventory and Analysis information is based on a sampling procedure designed to provide reliable statistics at the State level. Consequently, the reported figures are estimates only. The sampling errors shown below mean the chances are two out of three that the true inventory value is within the limits indicated.

For example, the estimated growing-stock volume in eastern South Dakota in 1980, 51.9 million cubic feet, has a sampling error of ±40.48 percent (±21.0 million cubic feet). Therefore, the growing-stock volume from a 100-percent inventory would have a two in three chance of falling between 30.9 and 72.9 million cubic feet.

The following tabulation shows the sampling errors for the 1980 eastern South Dakota Inventory:

Item	Unit totals	Sampling errors
Growing stock	(Million cubic feet)	(Percent)
Volume	51.9	40
Growth	1.5	53
Removals	1.8	27
Sawtimber	(Thousand board feet)	
Volume	176,400	30
Growth	7,548	46
Removals	5,571	25
Commercial forest	(Thousand acres)	
area	113.6	38

As survey data are broken down into sections smaller than Unit totals, the sampling error increases. The smaller the breakdown, the larger the sampling error. For example, the sampling error for growing-stock volume in a particular county is higher than that for total growing-stock volume in the Unit (table 69 shows the sampling errors for smaller estimates).

SURVEY PROCEDURE

The major steps in the survey of eastern South Dakota were as follows:

- 1. A total of 222,070 1-acre points were systematically distributed across aerial photos of the entire State. Photo interpretors classified these points as forest land (2,206), nonforest land with trees (2,170), nonforest land without trees (213,372), questionable (501), and water (3,713), in order to make a preliminary estimate of forest area. Next, all of the forest, nonforest with trees, and questionable points were stereoclassified as to forest type, stand-size class, and density. Then 254 points classed as forest, 69 points classed as questionable, and 248 points classed as nonforest with trees were examined on the ground to correct the preliminary area estimate for errors in classification and for actual changes in land use since the photos were taken. At each of 74 commercial forest locations, variable-radius plots (basal area factor 37.5) were established at 10 points uniformly placed over the sample acre. Twenty-four of these 74 locations were plots established during the 1965 survey and remeasured during the 1980 survey to provide improved growth and mortality information. Tree measurements made at commercial forest locations were the basis for estimates of timber volume, growth, mortality, number of trees, and other forest classifications.
- 2. Growth and mortality on commercial forest land were estimated using data collected on remeasurement plots (those established in 1965 and remeasured in 1980) and on new plots established in 1980. On

remeasurement plots growth was calculated as the observed change in volume on surviving trees. On new plots the remeasurement data and the Stand and Tree Evaluation and Modeling System (STEMS)³ were used to estimate growth. STEMS is a system of computer programs that projects the growth of individual trees in stands. Mortality was measured on remeasurement plots as the observed volume in trees that died between surveys. On new plots, mortality was estimated by determining the volume in trees that died within 3 years of plot establishment. Growth and mortality were converted to an annual basis.

- 3. Statistics on timber utilization during 1979 were obtained from mill surveys. The South Dakota Department of Wildlife, Parks, and Forestry (SDDWPF) canvassed resident sawmills and other primary woodusing plants. The North Central Forest Experiment Station canvassed out-of-State primary wood-using mills such as sawmills and veneer mills to determine their use of timber from South Dakota. The SDDWPF canvassed 1,343 randomly selected households to estimate 1979 fuelwood and post production from roundwood. Estimates of primary mill residue used for fuelwood were obtained from the canvass of South Dakota primary wood-using plants. Timber cut for products by ownership class was determined by a canvass of public and industrial timber owners. The portion of timber cut unaccounted for by the latter owners was grouped under "farmer and other owners".
- 4. Wood utilization factors for converting timber products output to timber removals for saw logs were obtained during the 1975-1976 Minnesota utilization study. Factors for fuelwood and posts were obtained during the 1964 South Dakota utilization study.
- 5. Field data were sent to St. Paul, Minnesota for processing and analysis.

COMPARING EASTERN SOUTH DAKOTA'S THIRD SURVEY WITH THE SECOND SURVEY

Data from new forest surveys are often compared with data from earlier ones to determine trends in forest areas and volumes. Changes in procedures and definitions between surveys make it necessary to adjust earlier survey data so they are comparable to data from the new survey.

The published 1965 area of commercial forest land, 222,900 acres, was adjusted due to some definitional changes between surveys. Some land now defined as wooded pasture was defined as commercial forest land in 1965. Also, new site productivity curves for ponderosa pine caused some land previously classified as commercial to be classified as unproductive forest land in the current survey. The adjusted 1965 area, 165,400 acres, can be compared directly with the 1980 area (113,600 acres).

The Timber Resource Analysis System (a USDA Forest Service computer program for updating, backdating, and projecting timber volume, growth, mortality, and removals) recalculated 1965 volumes using 1980 estimates of cubic foot volume per tree and 1980 board foot-cubic foot ratios. This volume adjustment was necessary so that volume differences between surveys represented actual change and not merely change in the volume equations used on each occasion.

LOG GRADE

In eastern South Dakota the butt log of every sawtimber tree was graded for quality. Logs were graded on the basis of external characteristics. Hardwood species were graded according to "Hardwood Log Grades for Standard Lumber." The best 12-foot section of the lowest 16-foot hardwood log, or the best 12-foot upper section if the butt log did not meet minimum log-grade standards, was graded as follows:

³Belcher, David M.; Holdaway, Margaret R.; Brand, Gary J. A description of STEMS—the stand and tree evaluation and modeling system. Gen. Tech. Rep. NC-79. St. Paul, MN. U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station; 1982. 18 p.

⁴Vaughn, C.L.; Wollin, C.A.; McDonald, K.A.; Bulgrin, E.H. Hardwood log grades for standard lumber. Res. Pap FPL-63, Madison, WI: U.S. Department of Agriculture, Forest Service, Forest Products Laboratory; 1966. 52 p.

Forest Service standard grades for hardwood factory saw logs

			-		Speci	fications			
Grading factors			Log grade 1			Log g	rade 2		Log grade 3
Position in tree		Butts only		tts and ppers		Bu	itts and up	pers	Butts and uppers
Scaling diameter, inc	ches	113-15	16-19	20+	² 11+		12+	-	8+
Length without trim,	feet		10+		10+	8-9	10-11	12+	8+
	Min. length, feet	7	5	3	3	3	3	3	2
Required	Max. number	2	2	2	2	2	2	3	No Limit
clear cuttings³ of each of three best faces⁴	Min. proportion of log length required in clear cutting	5/6	5/6	5/6	2/3	3/4	2/3	2/3	1/2
Maximum	For logs with less than one-fourth of end in sound defects		15 percent			30 percent			50 percent
sweep and crook allowance	For logs with more than one-fourth of end in sound defects		10 percent			20 pe	ercent		35 percent
Maximum scaling de	duction		40 percent⁵			50 pe	ercent ⁶		50 percent

 $^{^{1}}$ Ash and basswood butts can be 12 inches if they otherwise meet requirements for small #1's.

²Ten-inch logs of all species can be #2's if they otherwise meet requirements for small #1's.

³A clear cutting is a portion of a face, extending the width of the face, that is free of defects.

⁴A face is one-fourth of the surface of the log as divided lengthwise. ⁵Otherwise #1 logs with 41-60 percent deductions can be #2. ⁶Otherwise #2 logs with 51-60 percent deductions can be #3.

Forest Service standard specifications for hardwood construction logs (tie and timber logs)

Position in tree		Butt and upper
Min. diameter, small end		8 inches +
Min. length, without trim		8 feet
Clear cuttings		No requirements.
Sweep allowance, absolute)	One-fourth of the diameter at the small end for each 8 feet of length.
	Single knots	Any number, if no one knot has an average diameter above the callus in excess of one-third of the log diameter at point of occurrence.
Sound surface defects	Whorled knots	Any number if sum of knot diameters above the callus does not exceed one-third of the log diameter at point of occurrence.
	Holes	Any number provided none has a diameter over one- third of the log diameter at point of occurrence, and none extends more than 3 inches into included timber. ²
Unsound surface defects		Same requirements as for sound defects if they extend into included timber. ² No limit if they do not.
	Sound	No requirements.
End defects	Unsound	None allowed; log must be sound internally, but will admit one shake not to exceed one-fourth the scaling diameter and will admit a longitudinal split not extending more than 5 inches into the contained timber.

¹These specifications are minimum for the class. If, from a group of logs, factory logs are selected first, thus leaving only non-factory logs from which to select construction logs, then the quality range of the construction logs so selected is limited, and the class may be considered a grade. If selection of construction logs is given first priority, then it may be necessary to subdivide the class into grades.

²Included timber is always square, and dimension is judged from small end.

Softwood species were graded according to the following specifications:

LOG GRADES FOR SOFTWOOD LOGS

Grade 1

- 1. Logs must be 16 inches or larger, 10 feet or longer, and with deduction for defect not over 30 percent of gross scale.
- Logs must be at least 75 percent clear on each of three faces.
- 3. All knots outside clear cutting must be sound and not over 2-1/2 inches in diameter.

Grade 2

- 1. Logs must be 12 inches or larger, 10 feet or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.
- 2. Logs must be at least 50 percent clear on each of three faces or 75 percent clear on two faces.

Grade 3

CODUMICO

Logs must be 6 inches or larger, 8 feet or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.

Note: (A) Diameters are diameter inside bark at small end of log.

(B) Percent clear refers to percent clear in one continuous section.

METRIC EQUIVALENTS OF UNITS USED IN THIS REPORT

1 acre = 4.046.86 square meters or 0.405 hectare.

1,000 acres = 405 hectares.

1 cubic foot = 0.0283 cubic meter.

1 foot = 30.48 centimeters or 0.3048 meter.

1 inch = 25.4 millimeters, 2.54 centimeters, or 0.0254 meter.

DEFINITION OF TERMS

Acceptable trees.—Growing-stock trees of commercial species that meet specified standards of size and quality but do not qualify as desirable trees.

Area-condition classes.—*Class 10.*—Areas fully stocked with desirable trees but not overstocked.

Class 20.—Areas fully stocked with desirable trees but overstocked with all live trees.

Class 30.—Areas medium to fully stocked with desirable trees and with less than 30 percent of the area controlled by other trees and/or inhibiting vegetation or surface conditions that will prevent occupancy by desirable trees.

Class 40.—Areas medium to fully stocked with desirable trees and with 30 percent or more of the area controlled by other trees and/or conditions that ordinarily prevent occupancy by desirable trees.

Class 50.—Areas poorly stocked with desirable trees but fully stocked with growing-stock trees.

Class 60.—Areas poorly stocked with desirable trees but with medium to full stocking of growing-stock trees.

Class 70.—Areas poorly stocked with desirable trees and poorly stocked with growing-stock trees.

Basal area.—The area in square feet of the cross section at breast height of a single tree. When the basal area of all trees in a stand are summed, the result is usually expressed as square feet of basal area per acre.

Biomass.—The above-ground mass of all live trees (including bark and foliage). Biomass is made up of 5 components:

Growing-stock bole.—Biomass of a growing-stock tree from a 1-foot stump to a variable 4-inch top.

Growing-stock tops and limbs.—Biomass of a growing-stock tree from a 1-foot stump minus the growing-stock bole.

Cull bole.—Biomass of a cull tree from a 1-foot stump to a variable 4-inch top.

Cull tops and limbs.—Biomass of a cull tree from a 1-inch stump minus the cull bole.

1- to 5-inch trees.—Biomass of all live trees 1- to 5-inches in diameter at breast height.

Commercial forest land.—Forest land producing or capable of producing crops of industrial wood and not withdrawn from timber utilization. (Note: Areas qualifying as commercial forest land have the capability of producing in excess of 20 cubic feet per acre per year of annual growth under management. Currently inaccessible and inoperable areas are included, except when the areas involved are small and unlikely to become suitable for production of industrial wood in the foreseeable future.) Also see definition of pastured commercial forest land.

Commercial species.—Tree species presently or prospectively suitable for industrial wood products. (Note: Excludes species of typically small size, poor form, or inferior quality such as hophornbeam and hawthorn.)

County and municipal land.—Land owned by counties and local public agencies or municipalities, or land leased to these governmental units for 50 years or more.

Cropland.—Land under cultivation within the past 24 months, including cropland harvested, crop failures, cultivated summer fallow, idle cropland used only for pasture, orchards, and land in soil improvement crops, but excluding land cultivated in developing improved pasture.

Cull.—Portions of a tree that are unusable for industrial wood products, because of rot, poor form, or other defect.

Desirable trees.—Growing-stock trees having no serious defects in quality limiting present or prospective use, and of relatively high vigor, and containing no pathogens that may kill or seriously deteriorate before rotation age. These trees would be favored by forest managers in silvicultural operations.

Diameter classes.—A classification of trees based on diameter outside bark, measured at breast height (4-½ feet above the ground). (Note: D.b.h. is the common abbreviation for diameter at breast height. Two-inch diameter classes are commonly used in Forest Survey, with the even inch the approximate midpoint for a class. For example, the 6-inch class includes trees 5.0 through 6.9 inches d.b.h. inclusive.)

Farm.—Any land from which \$1,000 or more of agricultural products were produced and sold during the year.

Farmer-owned land.—Land owned by operators of farms. (Note: Excludes land leased by farm operators from nonfarm owners, such as railroad companies and States.)

Forest land.—Land at least 16.7 percent stocked by forest trees of any size, or formerly having had such tree cover, and not currently developed for nonforest use. (Note: Stocking is measured by comparison of basal area and/or number of trees, by age or size and spacing with specified standards). The minimum area for classification of forest land is 1 acre. Roadside, streamside, and shelterbelt strips of timber must have a crown width at least 120 feet wide to qualify as forest land. Unimproved roads and trails, streams, or other bodies of water or clearings in forest areas shall be classed as forest if less than 120 feet wide. Also see definitions of land area, commercial forest land, noncommercial forest land, productive-reserved forest land, stocking, unproductive forest land, nonforest land, and water.

Forest industry land.—Land owned by companies or individuals operating primary wood-using plants.

Forest trees.—Woody plants having a well developed stem and usually more than 12 feet in height at maturity.

Forest types.—A classification of forest land based upon the species forming a plurality of live tree stocking. Major forest types in Eastern South Dakota are:

Ponderosa pine.—Forests in which ponderosa pine comprises a plurality of the stocking.

Oak.—Forests in which bur oak comprises a plurality of the stocking. (Common associates include ash, basswood and elm.)

Plains hardwoods.—Forests in which black walnut, hackberry, and bur oak, singly or in combination, comprise a plurality of the stocking. Commonly found on slopes and uplands. Juniper is a common associate.

Elm-ash.—Forests in which elm, ash, cottonwood, and willow, singly or in combination, comprise a plurality of the stocking, except for those in which

cottonwood comprises a majority of the stocking. Found on first or second bottoms of major streams. *Cottonwood.*—Forests in which cottonwood comprises a majority of the stocking.

Gross area.—The entire area of land and water as determined by the Bureau of the Census, 1980.

Growing-stock trees.—Live trees of commercial species qualifying as desirable and acceptable trees. (Note: Excludes rough and rotten trees.)

Growing-stock volume.—Net volume in cubic feet of growing-stock trees 5.0 inches d.b.h. and over, from a 1-foot stump to a minimum 4.0 inch top diameter outside bark of the central stem, or to the point where the central stem breaks into limbs. Cubic feet can be converted to cords by dividing by 79 cubic feet per solid wood cord.

Hardwoods.—Dicotyledonous trees, usually broadleaved and deciduous.

Idle farmland.—Includes former cropland, orchards, improved pastures, and farm sites not tended within the past 2 years and presently less than 16.7 percent stocked with trees.

Improved pasture.—Land currently improved for grazing by domestic livestock by cultivation, seeding, irrigation, or clearing of trees or brush, and less than 16.7 percent stocked with live trees. This includes areas classified as range by the USDA Soil Conservation Service.

Indian land.—Tribal land held in fee but administered by the Federal Government.

Land area.—A. Bureau of the Census.—The area of dry land and land temporarily or partly covered by water, such as marshes, swamps, and river flood plains (omitting tidal flats below mean high tide); streams, sloughs, estuaries, and canals less than ½ of a statute mile in width; and lakes, reservoirs, and ponds less than 40 acres in area.

B. Forest Inventory and Analysis.—The same as the Bureau of the Census, except minimum width of streams, etc. is 120 feet and minimum size of lakes, etc. is 1 acre.

Live trees.—Growing-stock, rough, and rotten trees 1 inch d.b.h. and larger.

Log grades.—A classification of logs based on external characteristics as indicators of quality or value. (See Appendix for specific grading factors used.)

Logging residues.—The unused growing-stock portions of trees cut or killed by logging.

Maintained road.—Any road, that is plowed or graded at least once a year. Includes rights of way that are cut or treated to limit herbaceous growth.

Marsh.—Nonforest land that characteristically supports low, generally herbaceous or shrubby vegetation intermittently covered with water.

Merchantable.—Refers to a pulpwood or saw log section that meets pulpwood or saw log specifications, respectively.

Miscellaneous federal land.—Federal land other than National Forest, land administered by the Bureau of Land Management, and Indian land.

Miscellaneous private lands.—Privately owned land other than that owned by forest-industry or farmers.

Mortality.—The annual volume of sound wood in growing-stock and sawtimber trees that die.

National forest land.—Federal land that has been legally designated as National Forests or purchase units, and other land under the administration of the USDA Forest Service.

Net annual growth of growing-stock.—The annual change in volume of sound wood in livesawtimber and poletimber trees and the total volume of trees entering these classes through ingrowth, less volume losses resulting from natural causes.

Net annual growth of sawtimber.—The annual change in the volume of live sawtimber trees and the total volume of trees reaching sawtimber size, less volume losses resulting from natural causes.

Net volume.—Gross volume less deductions for rot, sweep, or other defect affecting use for timber products.

Noncommercial forest land.—Unproductive forest land and productive-reserved forest land. See definitions of unproductive and productive-reserved forest land.

Noncommercial species.—Tree species of typically small size, poor form, or inferior quality that normally do not develop into trees suitable for industrial wood products.

Nonforest land.—Land that has never supported forests, and land formerly forested where use for timber management is precluded by development for other uses. (Note: Includes areas used for crops, improved pasture, residential areas, city parks, improved roads of any width and adjoining clearings, powerline clearings of any width, and 1- to 40-acre areas of water classified by the Bureau of the Census as land. If intermingled in forest areas, unimproved roads and nonforest strips must be more than 120 feet wide, and more than 1 acre in size, to qualify as nonforest land.)

A. Nonforest land without trees.—Nonforest land with no live trees present.

B. Nonforest land with trees.—Nonforest land with one or more trees at least 5 inches in d.b.h. per acre.

Nonstocked land.—Commercial forest land less than 16.7 percent stocked with growing-stock trees.

Other removals.—Growing-stock trees removed but not utilized for products, or trees left standing but "removed" from the commercial forest land classification by land use change. Examples are removals from cultural operations such as timber stand improvement work, land clearing, and changes in land use.

Ownership.—Property owned by one owner, regardless of the number of parcels in a specified area.

Ownership size class.—The amount of commercial forest land owned by one owner, regardless of the number or parcels.

Owner tenure.—The length of time a property has been held by the owner.

Pastured commercial forest land.— Commercial forest land presently used for grazing but for which the primary use is wood production.

Physiographic class.—A measure of soil and water conditions that affect tree growth on a site. Physiographic classes used in Forest Inventory and Analysis inventories are:

Xeric sites.—very dry soils where excessive drainage seriously limits both growth and species occurrence.

Xeromesic sites.—Moderately dry soils where excessive drainage limits growth and species occurrence to some extent. Example: dry oak ridge.

Mesic sites.—Deep, well-drained soils. Growth and species occurrence are limited only by climate.

Hydromesic sites.—Moderately wet soils where insufficient drainage or infrequent flooding limits growth and species occurrence to some extent. Example: better drained bottomland hardwood sites.

Hydric sites.—Very wet sites where excess water seriously limits both growth and species occurrence. Example: wet, frequently flooded river bottoms.

Plant byproducts.—Plant residues used for products such as mulch, pulp chips, and fuelwood.

Plant residues.—Wood and bark materials generated at manufacturing plants during production of other products.

Poletimber stands.—(See stand-size class.)

Poletimber trees.—Growing-stock trees of commercial species at least 5.0 inches in d.b.h., but smaller than sawtimber size.

Productive-reserved forest land.—Forest land sufficiently productive to qualify as commercial forest land, but withdrawn from timber utilization through statute, administrative regulation, designation, or exclusive use for Christmas-tree production, as indicated by annual shearing.

Pulpwood.—Roundwood, chips from roundwood, and wood residue used to manufacture pulp and to

produce flakeboard products such as particleboard, waferboard, and oriented strand board.

Rotten trees.—Live trees of commercial species that do not contain at least one 12-foot saw log or two saw logs 8 feet or longer, now or prospectively because they do not meet Regional specifications for freedom from defect primarily because of rot; that is, when more than 50 percent of the cull volume in a tree is rotten.

Rough trees.—(a) Live trees of commercial species that do not contain at least one merchantable 12-foot saw log or two saw logs 8 feet or longer, now or prospectively because they do not meet Regional specifications for freedom from defect primarily due to roughness or poor form, and (b) all live trees of noncommercial species.

Roundwood products.—Logs, bolts, or other round sections (including chips from roundwood) cut from trees for industrial or consumer uses. (Note: Includes saw logs; veneer logs and bolts; cooperage logs and bolts; pulpwood; fuelwood; piling; poles; posts; hewn ties; mine timbers; and various other round, split, or hewn products.)

Salvable dead trees.—Standing or down dead trees considered merchantable by Regional standards.

Saplings.—Live trees 1.0 inch to 5.0 inches in d.b.h. Sapling-seedling stands.—(See stand-size class.)

Saw log.—A log meeting minimum standards of diameter, length and defect, including logs at least 8 feet long, sound and straight and with a minimum diameter outside bark (d.o.b.) for softwoods of 7 inches (9 inches for hardwoods) or other combinations of size and defect specified by Regional standards.

Saw log portion.—That part of the bole of sawtimber trees between the stump and the saw log top.

Saw log top.—The point on the bole of sawtimber trees above which a saw log cannot be produced. The minimum saw log top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

Sawtimber stands.—(See stand-size class.)

Sawtimber trees.—Growing-stock trees of commercial species containing at least a 12-foot saw log or two noncontiguous saw logs 8 feet or longer, and meeting Regional specifications for freedom from defect. Softwoods must be at least 9.0 inches in d.b.h. Hardwoods must be at least 11.0 inches in d.b.h.

Sawtimber volume.—Net volume of the saw log portion of live sawtimber in board feet, International ¼-inch rule, from stump to a minimum 7.0 inches top d.o.b. for softwoods and a minimum 9.0 inches top d.o.b. for hardwoods.

Seedlings.—Live trees less than 1.0 inch in d.b.h. that are expected to survive. Only softwood seedlings

more than 6 inches tall and hardwood seedlings more than 1 foot tall are counted.

Short-log (rough tree).—Live trees of commercial species that contain at least one merchantable 8- to 11-foot saw log but not a 12-foot saw log, now or prospectively.

Shrub biomass.—The total above-ground volume (including the bark) of selected shrubs and trees less than 1-inch d.b.h.

Site classes.—A classification of forest land in terms of inherent capacity to grow crops of industrial wood based on fully stocked natural stands.

Site index.—An expression of forest site quality based on the height of a free-growing dominant or codominant tree of a representative species in the forest type at age 50.

Softwoods.—Coniferous trees, usually evergreen, having needles or scale like leaves.

Stand.—A growth of trees on a minimum of 1 acre of forest land that is stocked by forest trees of any size.

Stand-age class.—Age of the main stand. Main stand refers to trees of the dominant forest type and stand-size class.

Stand-area class.—The extent of a continuous forested area of the same forest type, stand-size class, and stand-density class.

Stand-size class.—A classification of forest land based on the size class of growing-stock trees on the area; that is, sawtimber, poletimber or seedlings and saplings.

A. Sawtimber stands.—Stands at least 16.7 percent stocked with growing-stock trees, with half or more of total stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

B. Poletimber stands.—Stands at least 16.7 percent stocked with growing-stock trees of which half or more of this stocking is in poletimber and/or sawtimber trees, and with poletimber stocking exceeding that of sawtimber.

C. Sapling-seedling stands.—Stands at least 16.7 percent stocked with growing-stock trees of which more than half of the stocking is saplings and/or seedlings.

D. *Nonstocked stands*.—Stands in which stocking of growing-stock trees is less than 16.7 percent.

State land.—Land owned by states, or land leased to these governmental units for 50 years or more.

Stocking.—The degree of occupancy of land by trees, measured by basal area and/or the number of trees in a stand by size or age and spacing, compared to the basal area and/or number of trees required to fully utilize the growth potential of the land; that is, the stocking standard.

A stocking percent of 100 indicates full utilization of the site and is equivalent to 80 square feet of basal area per acre in trees 5 inches d.b.h. and larger. In a stand of trees less than 5 inches d.b.h., a stocking percent of 100 would indicate that the present number of trees is sufficient to produce 80 square feet of basal area per acre when the trees reach 5 inches d.b.h.

Stands are grouped into the following stocking classes:

Overstocked stands.—Stands in which stocking of trees is 134.0 percent or more.

Fully stocked stands.—Stands in which stocking of trees is from 101.0 to 133.9 percent.

Medium stocked stands.—Stands in which stocking of trees is from 61.0 to 100.9 percent.

Poorly stocked stands.—Stands in which stocking of trees is from 16.7 to 60.9 percent.

Nonstocked areas.—Commercial forest land on which stocking of trees is less than 16.7 percent.

Timber removals from growing stock.—The volume of sound wood in growing-stock trees removed annually for forest products (including roundwood products and logging residues) and for other removals.

Timber removals from sawtimber.—The net boardfoot volume of live sawtimber trees removed for forest products annually (including roundwood products and logging residues) and for other removals.

Timber products output.—All timber products cut from roundwood and byproducts of wood manufacturing plants. Roundwood products include logs, bolts, or other round sections cut from growing-stock trees, cull trees, salvable dead trees, trees on nonforest land, noncommercial species, sapling-size trees, and limbwood. Byproducts from primary manufacturing plants include slabs, edgings, trimmings, miscuts, sawdust, shavings, veneer cores and clippings, and screenings of pulpmills that are used as pulpwood chips or other products.

Unproductive forest land.—Forest land incapable of producing 20 cubic feet per acre of annual growth or of yielding crops of industrial wood under natural conditions because of adverse site conditions. (Note: Adverse conditions include shallow soils, dry climate, poor drainage, high elevation, steepness, and rockiness.)

Upper stem portion.—That part of the bole of sawtimber trees above the saw log top to a minimum top diameter of 4.0 inches outside bark or to the point where the central stem breaks into limbs.

Urban and other areas.—Areas within the legal boundaries of cities and towns; suburban areas developed for residential, industrial, or recreational

purposes; schoolyards; cemeteries; roads; railroads; airports; beaches; powerlines and other rights-of-way; or other nonforest land not included in any other specified land-use class.

Water.—(a) Bureau of the Census.—Streams, sloughs, estuaries, and canals more than ½ of a statute mile in width; and lakes, reservoirs, and ponds more than 40 acres in area.

(b) Noncensus.—The same as the Bureau of the Census, except minimum width of streams, etc. is 120 feet and minimum size of lakes, etc. is 1 acre.

Windbreak.—A group of trees less than 120 feet wide used for protecting soil, cropfields, and buildings in use.

Wooded pasture.—Improved pasture with more than 16.7 percent stocking in live trees, but less than 25 percent stocking in growing-stock trees. Area is currently improved for grazing or there is other evidence of grazing. (Nonforest land with trees).

Wooded strips.—An acre or more of natural continuous forest land that would otherwise meet survey standards for commercial forest land except that it is less than 120 feet wide. (Nonforest land with trees).

Raile, Gerhard K.

Eastern South Dakota forest statistics, 1980. Resour. Bull. NC-74. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station; 1984. 60 p.

The third forest resource inventory of eastern South Dakota showed a 31 percent decline in commercial forest area and 42 percent loss in growing-stock volume between 1965 and 1980.

KEY WORDS: Area, volume, growth, mortality, removals.
